INTRO

This manual is meant to be a reference guide for cracking tool usage and supportive tools that assist network defenders and pentesters in password recovery (cracking). This manual will not be covering the installation of these tools, but will include references to their proper installation, and if all else fails, Google. Updates and additions to this manual are planned yearly as advancements in cracking evolve. Password recovery is a battle against math, time, cost, and human behavior; and much like any battle, the tactics are constantly evolving.

ACKNOWLEDGEMENTS

This community would not enjoy the success and diversity without the following community members and contributors:

Alexander ‘Solar Designer’ Peslvak, John The Ripper Team, & Community
Jens ‘atom’ Steube, Hashcat Team, & Devoted Hashcat Forum Community
Jeremi ‘epixoip’ Gosney
Korelogic & the Crack Me If You Can Contest
Robin ‘DigiNinja’ Wood (Pipal & CeWL)
CynoSure Prime Team
Chris ‘Unix-ninja’ Aurelio
Per Thorsheim (PasswordsCon)
Blandyuk & Rurapenthe (HashKiller Contest)
Peter ‘iphelix’ Kacherginsky (PACK)
Royce ‘tychotithonus’ Williams
‘Waffle’

And many, many, many more contributors. If a name was excluded from the above list please reach out and the next version will give them their due credit.

Lastly, the tools, research, and resources covered in the book are the result of people’s hard work. As such, I HIGHLY encourage all readers to DONATE to help assist in their efforts. A portion of the proceeds from this book will be distributed to

the various researchers/projects.

Suggestions or comments, send your message to hashcrack@netmux.com

REQUIRED SOFTWARE

In order to follow many of the techniques in this manual, you will want to install the following software on your Windows or *NIX host. This book does not cover how to install said software and assumes you were able to follow the included links and extensive support websites.

HASHCAT v3.6 (or newer)

<https://hashcat.net/hashcat/>

JOHN THE RIPPER (v1.8.0 JUMBO)

<http://www.openwall.com/john/>

PACK V0.0.4 (Password Analysis and Cracking Toolkit)

<http://thesprawl.org/projects/pack/>

Hashcat-utils v1.7

https://hashcat.net/wiki/doku.php?id=hashcat_utils

Additionally you will need dictionaries/wordlists and highly recommend the below sources:

WEAKPASS DICTIONARY

<https://weakpass.com/wordlist>

CRACKSTATION DICTIONARY

<https://crackstation.net/buy-crackstation-wordlist-password-cracking-dictionary.htm>

SKULL SECURITY WORDLISTS

<https://wiki.skullsecurity.org/index.php?title=Passwords>

Throughout the manual, generic names have been given to the various inputs required in a cracking commands structure. Legend description is below:

COMMAND STRUCTURE LEGEND

hashcat = Generic representation of the various Hashcat binary names
john = Generic representation of the John the Ripper binary names
#type = Hash type; which is an abbreviation in John or a number in Hashcat
hash.txt = File containing target hashes to be cracked
dict.txt = File containing dictionary/wordlist
rule.txt = File containing permutation rules to alter dict.txt input
passwords.txt = File containing cracked password results
outfile.txt = File containing results of some functions output

Lastly, as a good reference for testing various hash types to place into your “hash.txt” file, the below sites contain all the various hashing algorithms and example output tailored for each cracking tool:

HASHCAT HASH FORMAT EXAMPLES

https://hashcat.net/wiki/doku.php?id=example_hashes

JOHN THE RIPPER HASH FORMAT EXAMPLES

<http://pentestmonkey.net/cheat-sheet/john-the-ripper-hash-formats>

<http://openwall.info/wiki/john/sample-hashes>

CORE HASH CRACKING KNOWLEDGE

ENCODING vs HASHING vs ENCRYPTING

Encoding = transforms data into a publicly known scheme for usability

Hashing = one-way cryptographic function nearly impossible to reverse

Encrypting = mapping of input data and output data reversible with a key

CPU vs GPU

CPU = 2-72 cores mainly optimized for sequential serial processing

GPU = 1000's of cores with 1000's of threads for parallel processing

CRACKING TIME = KEYSIZE / HASHRATE

Keyspace: charset^{length} (?a?a?a?a = 95⁴ = 81,450,625)

Hashrate: hashing function / hardware power (bcrypt / GTX1080 = 13094 H/s)

Cracking Time: 81,450,625 / 13094 H/s = 6,220 seconds

*Keyspace displayed and Hashrate vary by tool and hardware used

SALT = random data that's used as additional input to a one-way function

ITERATIONS = the number of times an algorithm is run over a given hash

HASH IDENTIFICATION: there isn't a foolproof method for identifying which hash function was used by simply looking at the hash, but there are reliable clues (i.e. \$6\$ sha512crypt). The best method is to know from where the hash was extracted and identify the hash function for that software.

DICTIONARY/WORDLIST ATTACK = straight attack uses a precompiled list of words, phrases, and common/unique strings to attempt to match a password.

BRUTE-FORCE ATTACK = attempts every possible combination of a given character set, usually up to a certain length.

RULE ATTACK = generates permutations against a given wordlist by modifying, trimming, extending, expanding, combining, or skipping words.

MASK ATTACK = a form of targeted brute-force attack by using placeholders for

characters in certain positions (i.e. ?a?a?a?l?d?d).

HYBRID ATTACK = combines a Dictionary and Mask Attack by taking input from the dictionary and adding mask placeholders (i.e. dict.txt ?d?d?d).

CRACKING RIG = from a basic laptop to a 64 GPU cluster, this is the hardware/platform on which you perform your password hash attacks.

EXPECTED RESULTS

Know your cracking rig's capabilities by performing benchmark testing and don't assume you can achieve the same results posted by forum members without using the exact same dictionary, attack plan, or hardware setup. Cracking success largely depends on your ability to use resources efficiently and make calculated trade-offs based on the target hash.

DICTIONARY/WORDLIST vs BRUTE-FORCE vs ANALYSIS

Dictionaries and brute-force are not the end all be all to crack hashes. They are merely the beginning and end of an attack plan. True mastery is everything in the middle, where analysis of passwords, patterns, behaviors, and policies affords the ability to recover that last 20%. Experiment with your attacks and research and compile targeted wordlists with your new knowledge. Do not rely heavily on dictionaries because they can only help you with what is "known" and not the unknown.

CRACKING METHODOLOGY

Following is basic cracking methodology broken into steps, but the process is subject to change based on current/future target information uncovered during the cracking process.

1-EXTRACT HASHES

Pull hashes from target, identify hashing function, and properly format output for your tool of choice.

2-FORMAT HASHES

Format your hashes based on your tool's preferred method. See tool documentation for this guidance. Hashcat, for example, on each line takes <user>:<hash> OR just the plain <hash>.

3-EVALUATE HASH STRENGTH

Using the [Appendix](#) table “Hash Cracking Speed (Slow-Fast)” assess your target hash and it’s cracking speed. If it’s a slow hash, you will need to be more selective at what types of dictionaries and attacks you perform. If it’s a fast hash, you can be more liberal with your attack strategy.

4-CALCULATE CRACKING RIG CAPABILITIES

With the information from evaluating the hash strength, baseline your cracking rig’s capabilities. Perform benchmark testing using John The Ripper and/or Hashcat’s built-in benchmark ability on your rig.

john --test

hashcat -b

Based on these results you will be able to better assess your attack options by knowing your rigs capabilities against a specific hash. This will be a more accurate result of a hash’s cracking speed based on your rig. It will be useful to save these results for future reference.

5-FORMULATE PLAN

Based on known or unknown knowledge begin creating an attack plan. Included on the next page is a “Basic Cracking Playbook” to get you started.

6-ANALYZE PASSWORDS

After successfully cracking a sufficient amount of hashes analyze the results for any clues or patterns. This analysis may aid in your success on any remaining hashes.

7-CUSTOM ATTACKS

Based on your password analysis create custom attacks leveraging those known clues or patterns. Examples would be custom mask attacks or rules to fit target users' behavior or preferences.

8-ADVANCED ATTACKS

Experiment with Princeprocessor, custom Markov-chains, maskprocessor, or custom dictionary attacks to shake out those remaining stubborn hashes. This is where your expertise and creativity really come into play.

9-REPEAT

Go back to STEP 4 and continue the process over again, tweaking dictionaries, mask, parameters, and methods. You're in the grind at this point and need to rely on skill and luck.

BASIC CRACKING PLAYBOOK

This is only meant as a basic guide to processing hashes and each scenario will obviously be unique based on external circumstances. For this attack plan we will assume we know the password hashes are raw MD5 and assume we have already captured some plain text passwords of users. If we had no knowledge of plain text passwords we would most likely skip to DICTIONARY/WORDLIST attacks. Lastly, since MD5 is a “Fast” hash we can be more liberal with our attack plan.

1-CUSTOM WORDLIST

First compile your known plain text passwords into a custom wordlist file. Pass this to your tool of choice as a straight dictionary attack.

```
hashcat -a 0 -m 0 -w 4 hash.txt custom_list.txt
```

2-CUSTOM WORDLIST + RULES

Run your custom wordlist with permutation rules to crack slight variations.

```
hashcat -a 0 -m 0 -w 4 hash.txt custom_list.txt -r best64.rule --loopback
```

3 -DICTIONARY/WORDLIST

Perform a broad dictionary attack, looking for common passwords and leaked passwords in well known dictionaries/wordlists.

```
hashcat -a 0 -m 0 -w 4 hash.txt dict.txt
```

4-DICTIONARY/WORDLIST + RULES

Add rule permutations to the broad dictionary attack, looking for subtle changes to common words/phrases and leaked passwords.

```
hashcat -a 0 -m 0 -w 4 hash.txt dict.txt -r best64.rule --loopback
```

5-CUSTOM WORDLIST + RULES

Add any newly discovered passwords to your custom wordlist and run an attack again with permutation rules, looking any other subtle variations.

```
awk -F ":" '{print $2}' hashcat.potfile >> custom_list.txt  
hashcat -a 0 -m 0 -w 4 hash.txt custom_list.txt -r dive.rule --loopback
```

6-MASK

Now we will use mask attacks included with Hashcat to search the keyspace for common password lengths and patterns, based on the RockYou dataset.

```
hashcat -a 3 -m 0 -w 4 hash.txt rockyou-1-60.hcmask
```

7-HYBRID DICTIONARY + MASK

Using a dictionary of your choice, conduct hybrid attacks looking for larger variations of common words or known passwords by appending/prepending masks to those candidates.

```
hashcat -a 6 -m 0 -w 4 hash.txt dict.txt rockyou-1-60.hcmask  
hashcat -a 7 -m 0 -w 4 hash.txt rockyou-1-60.hcmask dict.txt
```

8-CUSTOM WORDLIST + RULES

Add any newly discovered passwords back to your custom wordlist and run an attack again with permutation rules looking any other subtle variations.

```
awk -F ":" '{print $2}' hashcat.potfile >> custom_list.txt  
hashcat -a 0 -m 0 -w 4 hash.txt custom_list.txt -r dive.rule --loopback
```

9-COMBO

Using a dictionary of your choice, perform a combo attack by individually combining the dictionary's password candidates together to form new candidates.

```
hashcat -a 1 -m 0 -w 4 hash.txt dict.txt dict.txt
```

10-CUSTOM HYBRID ATTACK

Add any newly discovered passwords back to your custom wordlist and perform a hybrid attack against those new acquired passwords.

```
awk -F ":" '{print $2}' hashcat.potfile >> custom_list.txt  
hashcat -a 6 -m 0 -w 4 hash.txt custom_list.txt rockyou-1-60.hcmask  
hashcat -a 7 -m 0 -w 4 hash.txt rockyou-1-60.hcmask custom_list.txt
```

11-CUSTOM MASK ATTACK

By now the easier, weaker passwords may have fallen to cracking, but still some remain. Using PACK (on [pg.51](#)) create custom mask attacks based on your currently cracked passwords. Be sure to sort out masks that match the previous rockyou-1-60.hcmask list.

```
hashcat -a 3 -m 0 -w 4 hash.txt custom_masks.hcmask
```

12-BRUTE-FORCE

When all else fails begin a standard brute-force attack, being selective as to how large a keyspace your rig can adequately brute-force. Above 8 characters this is typically pointless due to hardware limitations and password entropy/ complexity.

```
hashcat -a 3 -m 0 -w 4 hash.txt -i ?a?a?a?a?a?a?a?a
```

TERMINAL COMMAND CHEAT SHEET

Ctrl + u

delete everything from the cursor to the beginning of the line

Ctrl + w

delete the previous word on the command line before the cursor

Ctrl + l

clear the terminal window

Ctrl + a

jump to the beginning of the command line

Ctrl + e

move your cursor to the end of the command line

Ctrl + r

search command history in reverse, continue pressing key sequence to continue backwards search. Esc when done or command found.

FILE MANIPULATION CHEAT SHEET

Extract all lowercase strings from each line and output to wordlist.

sed 's/[^a-z]*//g' wordlist.txt > outfile.txt

Extract all uppercase strings from each line and output to wordlist.

sed 's/[^A-Z]*//g' wordlist.txt > outfile.txt

Extract all lowercase/uppercase strings from each line and output to wordlist.

sed 's/[^a-zA-Z]*//g' wordlist.txt > outfile.txt

Extract all digits from each line in file and output to wordlist.

sed 's/[^\d]*//g' wordlist.txt > outfile.txt

Watch hashcat potfile or designated output file live.

watch -n .5 tail -50 <hashcat.potfile or outfile.txt>

Pull 100 random samples from wordlist/passwords for visual analysis.

shuf -n 100 file.txt

Print statistics on length of each string and total counts per length.

awk '{print length}' file.txt | sort -n | uniq -c

Remove all duplicate strings and count how many times they are present; then sort by their count in descending order.

uniq -c file.txt | sort -nr

Command to create quick & dirty custom wordlist with length 1-15 character words from a designated website into a sorted and counted list.

curl -s <http://www.netmux.com> | sed -e 's/<[^>]*>/\g' | tr " " "\n" | tr -dc '[:alnum:]'\n\r' | tr '[:upper:]' '[:lower:]' | cut -c 1-15 | sort | uniq -c | sort -nr

MD5 each line in a file (Mac OSX).

while read line; do echo -n \$line | md5; done < infile.txt > outfile.txt

MD5 each line in a file (*Nix).

while read line; do echo -n \$line | md5sum; done < infile.txt | awk -F " " '{print \$1}' > outfile.txt

Remove lines that match from each file and only print remaining from file2.txt.

grep -vwF -f file1.txt file2.txt

Take two ordered files, merge and remove duplicate lines and maintain ordering.

nl -ba -s ':\n' file1.txt >> outfile.txt

nl -ba -s ':\n' file2.txt >> outfile.txt

sort -n outfile.txt | awk -F ":" '{print \$2}' | awk '!seen[\$0]++' > final.txt

Extract strings of a specific length into a new file/wordlist.

awk 'length == 8' file.txt > 8len-out.txt

Convert alpha characters on each line in file to lowercase characters.

tr [A-Z] [a-z] < infile.txt > outfile.txt

Convert alpha characters on each line in file to uppercase characters.

tr [a-z] [A-Z] < infile.txt > outfile.txt

Split a file into separate files by X number of lines per outfile.

```
split -d -l 3000 infile.txt outfile.txt
```

Reverse the order of each character of each line in the file.

```
rev infile.txt > outfile.txt
```

Sort each line in the file from shortest to longest.

```
awk '{print length,$0}' "" $0; }' infile.txt | sort -n | cut -d ' ' -f2-
```

Sort each line in the file from longest to shortest.

```
awk '{print length,$0}' "" $0; }' infile.txt | sort -r -n | cut -d ' ' -f2-
```

Substring matching by converting to HEX and then back to ASCII.

(Example searches for **5** character strings from file1.txt found as a substring in **20** character strings in file2.txt)

```
strings file1.txt | xxd -u -ps -c 5 | sort -u > out1.txt
```

```
strings file2.txt | xxd -u -ps -c 20 | sort -u > out2.txt
```

```
grep -Ff out1.txt out2.txt | xxd -r -p > results.txt
```

Clean dictionary/wordlist of newlines and tabs.

```
cat dict.txt | tr -cd "[[:print :]]/[[:n/t]]\n" > outfile.txt
```

EXTRACT HASHES

SYSTEM HASH EXTRACTION

WINDOWS

METERPRETER HASHDUMP

Post exploitation dump local SAM database:

```
meterpreter> run post/windows/gather/hashdump
```

CREDDUMP

<https://github.com/Neohapsis/creddump7>

Three modes of attack: **cachedump**, **lsadump**, **pwdump**

DUMP DOMAIN CACHED CREDENTIALS

Save Windows XP/Vista/7 registry hive tables

```
C:\WIND0WS\system32>reg.exe save HKLM\SAM sam_backup.hiv
```

```
C:\WIND0WS\system32>reg.exe save HKLM\SECURITY sec_backup.hiv
```

```
C:\WIND0WS\system32>reg.exe save HKLM\system sys_backup.hiv
```

Run creddump tools against the saved hive files:

```
cachedump.py <system hive> <security hive> <Vista/7>
```

(Vista/7)

```
cachedump.py sys_backup.hiv sec_backup.hiv true
```

(XP)

```
cachedump.py sys_backup.hiv sec_backup.hiv false
```

DUMP LSA SECRETS

```
lsadump.py sys_backup.hiv sec_backup.hiv
```

DUMP LOCAL PASSWORD HASHES

```
pwdump.py sys_backup.hiv sec_backup.hiv
```

MIMIKATZ

Post exploitation commands must be executed from SYSTEM level privileges.

```
mimikatz # privilege::debug  
mimikatz # token::whoami  
mimikatz # token::elevate  
mimikatz # lsadump::sam
```

Save Windows XP/Vista/7 registry tables

```
C:\WIND0WS\system32>reg.exe save HKLM\SAM sam_backup.hiv  
C:\WIND0WS\system32>reg.exe save HKLM\SECURITY  
C:\WIND0WS\system32>reg.exe save HKLM\system  
mimikatz # lsadump::sam SystemBkup.hiv SamBkup.hiv
```

***NIX**

Requires root level privileges.

cat /etc/shadow

Example *NIX sha512crypt hash

```
root:$6$52450745$k5ka2p8bFuSmoVTltz0yyuaREkkKBcCNqoDKzYiDL9RaE8
```

MAC OSX 10.5-10.7

Manual OSX Hash Extraction

```
dscl localhost -read /Search/Users/<username>|grep GeneratedUID|cut -c15-cat  
/var/db/shadow/hash/<GUID> | cut -c169-216 > osx_hash.txt
```

MAC OSX 10.8-10.12

Manual OSX Hash Extraction

```
sudo defaults read /var/db/dslocal/nodes/Default/users/<username>.plist  
ShadowHashData|tr -dc '0-9a-f'|xxd -p -r|plutil -convert xml1 - -o -
```

Scripted OSX Hash Extraction

HASHCAT

<https://gist.github.com/nueh/8252572>

```
sudo plist2hashcat.py /var/db/dslocal/nodes/Default/users/<username>.plist
```

JOHN

<https://github.com/truongkma/ctf-tools/blob/master/John/run/ml2john.py>

```
sudo ml2john.py /var/db/dslocal/nodes/Default/users/<username>.plist
```

PCAP HASH EXTRACTION

LOCAL NETWORK AUTHENTICATION

PCREDZ

Extracts network authentication hashes from pcaps.

Single pcap file:

Pcredz -f example.pcap

Multiple pcap files in a directory:

Pcredz -d /path/to/pcaps

Interface to listen on and collect:

Pcredz -i eth0

WPA/WPA2 PSK AUTHENTICATION

Capture the 4-way WPA/WPA2 authentication handshake.

AIRMON-NG / AIRODUMP-NG / AIREPLAY-NG

Step 1: Create monitoring interface mon0 Ex) interface wlan0

airmon-ng start wlan0

Step 2: Capture packets to file on target AP channel Ex) channel 11

airodump-ng mon0 --write capture.cap -c 11

Step 3: Start deauth attack against BSSID Ex) bb:bb:bb:bb:bb:bb

aireplay-ng --deauth 0 -a bb:bb:bb:bb:bb:bb mon0

Step 4: Wait for confirmation to appear at top of terminal:

CH 11][Elapsed: 25 s][<DATE / TIME)][WPA handshake: **

Step 5: Extract handshake into JOHN or HASHCAT format:

JOHN FORMAT EXTRACT

Step1: cap2hccap.bin -e '<ESSID>' capture.cap capture_out.hccap

Step2: hccap2john capture_out.hccap > jtr_capture

HASHCAT FORMAT EXTRACT

cap2hccapx.bin capture.cap capture_out.hccapx

MISC WLAN TOOLS

HCXTOOLS: capture and convert packets from wlan devices for use with Hashcat.

<https://github.com/ZerBea/hcxtools>

DATABASE HASH EXTRACTION

SQL queries require administrative privileges.

ORACLE 10g R2

**SELECT username, password FROM dba_users WHERE
username='<username>;'**

ORACLE 11g R1

**SELECT name, password, spare4 FROM sys.user\$ WHERE
name='<username>;'**

MySQL4.1 / MySQL5+

SELECT User, Password FROM mysql.user INTO OUTFILE '/tmp/hash.txt' ;

MSSQL(2012), MSSQL(2014)

SELECT SL.name,SL.password_hash FROM sys.sql_logins AS SL;

POSTGRES

SELECT username, passwd FROM pg_shadow;

MISCELLANEOUS HASH EXTRACTION

John The Ripper Jumbo comes with various programs to extract hashes:

NAME	DESCRIPTION
1password2john.py	1Password vault hash extract
7z2john.py	7zip encrypted archive hash extract
androidfde2john.py	Android FDE convert disks/images into JTR format
aix2john.py	AIX shadow file /etc/security/passwd
apex2john.py	Oracle APEX hash formating
bitcoin2john.py	Bitcoin old wallet hash extraction (check btcrecover)
blockchain2john.py	Blockchain wallet extraction
cisco2john.pl	Cisco config file ingestion/ extract

cracf2john.py	CRACF program crafc.txt files
dmg2john.py	Apple encrypted disk image
ecryptfs2john.py	eCryptfs disk encryption software
efs2john.py	Windows Encrypting File System (EFS) extract
encfs2john.py	EncFS encrypted filesystem userspace
gpg2john	PGP symmetrically encrypted files
hccap2john	Convert pcap capture WPA file to JTR format
htdigest2john.py	HTTP Digest authentication
ikescan2john.py	IKE PSK SHA256 authentication
kcdcdump2john.py	Key Distribution Center (KDC) servers
keepass2john	Keepass file hash extract
keychain2john.py	Processes input Mac OS X keychain files
keyring2john	Processes input GNOME Keyring files
keystore2john.py	Output password protected Java KeyStore files
known_hosts2john.py	SSH Known Host file
kwallet2john.py	KDE Wallet Manager tool to manage the passwords
ldif2john.pl	LDAP Data Interchange Format (LDIF)
lion2john.pl	Converts an Apple OS X Lion plist file
lion2john-alt.pl	
lotus2john.py	Lotus Notes ID file for Domino
luks2john	Linux Unified Key Setup (LUKS) disk encryption
mcafee_epo2john.py	McAfee ePolicy Orchestrator password generator
ml2john.py	Convert Mac OS X 10.8 and later plist hash
mozilla2john.py	Mozilla Firefox, Thunderbird, SeaMonkey extract
odf2john.py	Processes OpenDocument Format ODF files
office2john.py	Microsoft Office [97-03, 2007, 2010, 2013) hashes
openbsd_softraid2john.py	OpenBSD SoftRAID hash
openssl2john.py	OpenSSL encrypted files
pcap2john.py	PCAP extraction of various protocols
pdf2john.py	PDF encrypted document hash extract
pfx2john	PKCS12 files
putty2john	PuTTY private key format
pwsafe2john	Password Safe hash extract
racf2john	IBM RACF binary database files
radius2john.pl	RADIUS protocol shared secret

rar2john	RAR 3.x files input into proper format
sap2john.pl	Converts password hashes from SAP systems
sipdump2john.py	Processes sipdump output files into JTR format
ssh2john	SSH private key files
sshng2john.py	SSH-ng private key files
strip 2john.py	Processes STRIP Password Manager database
sxc2john.py	Processes SXC files
truecrypt_volume2john	TrueCrypt encrypted disk volume
uaf2john	Convert OpenVMS SYSUAF file to unix-style file
vncpcap2john	TightVNC/RealVNCpcapsvs c3.3, 3.7 and 3.8 RFB
wpapcap2john	Converts PCAP or IVS2 files to JtR format
zip2john	Processes ZIP files extracts hash into JTR format

PASSWORD ANALYSIS

PASSWORD ANALYSIS

HISTORICAL PASSWORD ANALYSIS TIPS

- The average password length is 7-9 characters.
- The average English word is 5 characters long.
- The average person knows 50,000 to 150,000 words.
- 50% chance a user's password will contain one or more vowels.
- Women prefer personal names in their passwords, and men prefer hobbies.
- Most likely to be used symbols: ~, !, @, #, \$, %, &, *, and ?
- If a number, it's usually a 1 or 2, sequential, and will likely be at the end.
- If more than one number it will usually be sequential or personally relevant.
- If a capital letter, it's usually the beginning, followed by a vowel.
- 66% of people only use 1 - 3 passwords for all online accounts.
- One in nine people have a password based on the common Top 500 list.
- Western countries use lowercase passwords and Eastern countries prefer digits.

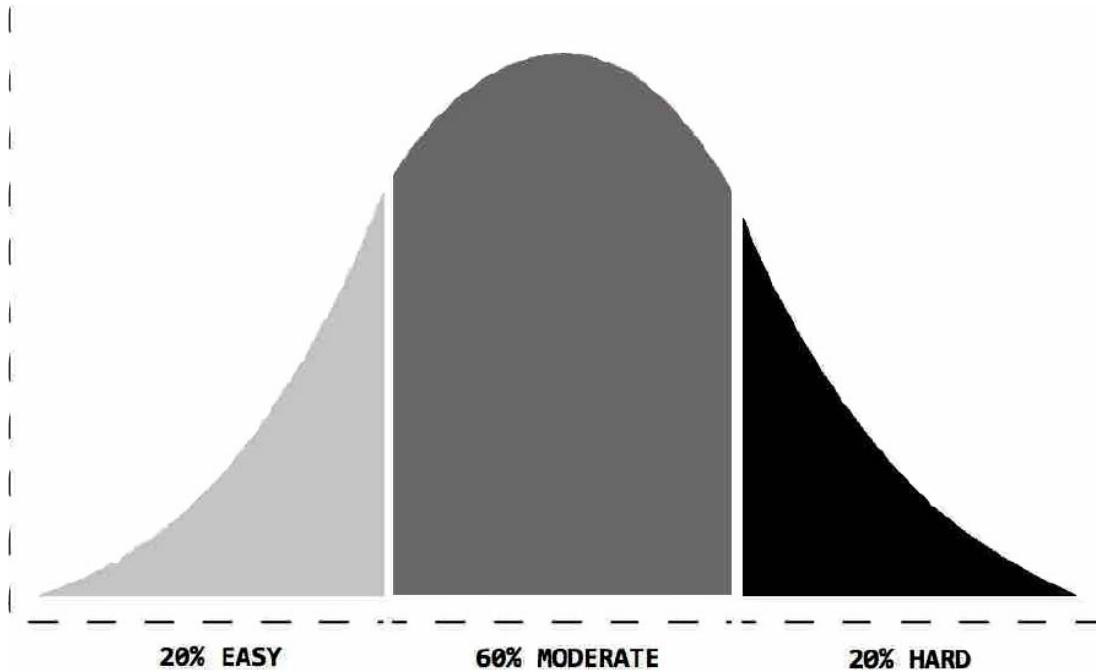

20-60-20 RULE

20-60-20 rule is a way to view the level of difficulty typically demonstrated by a large password dump, having characteristics that generally err on the side of a Gaussian Curve, mirroring the level of effort to recover said password dump.

20% of passwords are **easily** guessed dictionary words or known common passwords.

60% of passwords are **moderate** to slight variations of the earlier 20%.

20% of passwords are **hard**, lengthy, complex, or of unique characteristics.

EXAMPLE HASHES & PASSWORDS

This is an example list of passwords to help convey the variation and common complexities seen with typical password creation. It also shows individual user biases to aid in segmenting your attacks to be tailored toward a specific user.

#	<u>HASH (MySQL 323)</u>	<u>PASSWORD</u>	<u>MASK</u>

*This List of passwords will be referenced throughout the book and the List can also be found online at: <https://github.com/netmux/HASH-CRACK>

PASSWORD PATTERN ANALYSIS

A password can contain many useful bits of information related to its creator and their tendencies/patterns, but you have to break down the structure to decipher the meaning. This analysis process could be considered a sub-category of *Text Analytics*' and split into three pattern categories I'm calling:

Basic Pattern, Macro-Pattern, & Micro-Pattern.

*Refer to *EXAMPLE HASH & PASSWORDS* chapter (pg.29) for numbered examples.

Basic Pattern : visually obvious when compared to similar groupings (i.e. language and base word/words & digits). Let's look at Alice's passwords (2,5):

R0b3_rt2017!

Jennifer1981!

-Each password uses a name: R0b3rt & Jennifer

-Ending in a 4 digit date with common special character: **2017!** & **1981!**

!TIP! This type of basic pattern lends itself to a simple dictionary and L33T speak rule appending dates or hybrid mask attack appending Dict+ ?d?d?d?d?s

Macro-Pattern : statistics about the passwords underlying structure such as length and character set. Let's look at Craig's passwords (6,9):

7482Sacrifice

Solitaire7482

-Length structure can be summed up as: **4 Digits + 7 Alpha & 7 Alpha + 4 Digits**

-Uses charsets ?l?u?d , so we may be able to ignore special characters.

-Basic Pattern preference for the numbers **7482** and Micro-Pattern for capitalizing words beginning in "**S**".

!TIP! You can assume this user is 'unlikely' to have a password less than 12 characters (+1 char) and the 4 digit constant lowers the work to 8 chars. These examples lend themselves to a Hybrid Attack (Dict + 7482) or (7482 + Dict).

Micro-Pattern : subtlety and context which expresses consistent case changes, themes, and personal data/interest. Let's look at Bob's passwords (1,4)

BlueParrot345

RedFerret789

-Each password begins with a color: Blue & Red

-Second word is a type of animal: **Parrot** & **Ferret**

-Consistent capitalization of all words

-Lastly, ending in a 3 digit sequential pattern: **345** & **789**

!TIP! This pattern lends itself to a custom combo dictionary and rule or hybrid mask attack appending sequential digits ?d?d?d

So when analyzing passwords be sure to group passwords and look for patterns such as language, base word/digit, length, character sets, and subtle themes with possible contextual meaning or password policy restrictions.

WESTERN COUNTRY PASSWORD ANALYSIS

Password Length Distribution based on large corpus of English website dumps:

7=15% 8=27% 9=15% 10=12% 11=4.8% 12=4.9% 13=.6%

Character frequency analysis of a large corpus of English texts:

etaooinshrdlcumwfgypbvkjxqz

Character frequency analysis of a large corpus of English password dumps:

aeionrlstmcdyhubkgpjvfwzxq

Top Western password masks out of a large corpus of English website dumps:

?1?1?1?1?1?1	6-Lowercase
?1?1?1?1?1?1?1	7-Lowercase
?1?1?1?1?1?1?1?1	8-Lowercase
?d?d?d?d?d?d	6-Digits
?1?1?1?1?1?1?1?1?1?1?1?1?1?1?1?1	12-Lowercase

?d?d?d?d?d?d?d?d?d	12-Digits

PASSWORD MANAGER ANALYSIS

Apple Safari Password Generator

-default password 15 characters with “-” & four groups of three random
u=ABCDEFGHIJKLMNPQRSTUVWXYZ l=abcdefghijklmnoprstuvwxyz and
d=3456789

Example) **X9z-2Qp-3qm-WGN**

XXX-XXX-XXX-XXX where X = ?u?l?d

Dashlane

-default password 12 characters using just letters and digits.

Example) **Up0k9ZAj54Kt**

XXXXXXXXXXXXXX where X = ?u?l?d

KeePass

-default password 20 characters using uppercase, lowercase, digits, and special.

Example) **\$Zt={EcgQ.Umf)R,C7XF**

XXXXXXXXXXXXXXXXXXXX where X = ?u?l?d?s

LastPass

-default password 12 characters using at least one digit, uppercase and lowercase.

Example) **msfNdkG29n38**

XXXXXXXXXXXXXX where X = ?u?l?d

RoboForm

-default password 15 characters using uppercase, lowercase, digits, and special with a minimum of 5 digits.

Example) **871v2%%4F0w31zJ**

XXXXXXXXXXXXXXX where X = ?u?l?d?s

Symantec Norton Identity Safe

-default password 8 characters using uppercase, lowercase, and digits.

Example) **Ws81f0Zg**

XXXXXXX where X = ?u?l?d

True Key

-default password 16 characters using uppercase, lowercase, digits, and special.

Example) **1B1H:9N+@>+sgWs**

XXXXXXXXXXXXXXX where X = ?u?l?d?s

1Password v6

-default password 24 characters using uppercase, lowercase, digits, and special.

Example) **cTmM7Tzm6iPhCdpMu. * V] , VP**

XXXXXXXXXXXXXXXXXXXXXX where X = ?u?l?d?s

PACK (Password Analysis and Cracking Kit)

<http://thesprawl.org/projects/pack/>

STATSGEN

Generate statistics about the most common length, percentages, character-set and other characteristics of passwords from a provided list.

python statsgen.py passwords.txt

STATSGEN OPTIONS

-o <file.txt>	output stats and masks to file
--hiderare	hide stats of passwords with less than 1% of occurrence
--minlength=	minimum password length for analysis
--maxlength=	maximum password length for analysis

--charset= password char filter: loweralpha, upperalpha, numeric, special
--simplemask= password mask filter: string, digit, special

STATSGEN EXAMPLES

Output stats of passwords.txt to file example.mask:

python statsgen.py passwords.txt -o example.mask

Hide less than 1% occurrence; only analyze passwords 7 characters and greater:

python statsgen.py passwords.txt --hiderare --minlength=7 -o example.mask

Stats on passwords with only numeric characters:

python statsgen.py passwords.txt --charset=numeric

ZXCVBN (LOW-BUDGET PASSWORD STRENGTH ESTIMATION)

A realistic password strength (entropy) estimator developed by Dropbox.

<https://github.com/dropbox/zxcvbn>

PIPAL (THE PASSWORD ANALYSER)

Password analyzer that produces stats and pattern frequency analysis.

<https://digi.ninja/projects/pipal.php>

pipal.rb -o outfile.txt passwords.txt

PASSPAT (PASSWORD PATTERN IDENTIFIER)

Keyboard pattern analysis tool for passwords. <https://digi.ninja/projects/passpat.php>

passpat.rb --layout us passwords.txt

CHARACTER FREQUENCY ANALYSIS

Character frequency analysis is the study of the frequency of letters or groups of letters in a corpus/text. This is the basic building block of Markov chains.

Character-Frequency-CLI-Tool

Tool to analyze a large list of passwords and summarize the character frequency.
<https://github.com/jcchurch/Character-Frequency-CLI-Tool>

charfreq.py <options> passwords.txt

Options:

- w Window size to analyze, default=1
- r Rolling window size
- s Skip spaces, tabs, newlines

ONLINE PASSWORD ANALYSIS RESOURCES

WEAKPASS

Analyzes public password dumps and provides efficient dictionaries for download.

<http://weakpass.com/>

PASSWORD RESEARCH

Important password security and authentication research papers in one place.

<http://www.passwordresearch.com/>

THE PASSWORD PROJECT

Compiled analysis of larger password dumps using PIPAL and PASSPAL tools.

http://www.thepasswordproject.com/leaked_password_lists_and_dictionaries

DICTIONARY / WORDLIST

DICTIONARY / WORDLIST

CAPSOP

<https://wordlists.capsop.com/>

UNIX-NINJA DNA DICTIONARY

Dictionary link at bottom of article

https://www.unix-ninja.com/p/Password_DNA

PROBABLE-WORDLIST

<https://github.com/berzerk0/Probable-Wordlists>

EFF-WORDLIST

Long-list (7,776 words) & Short-list (1,296 words)

https://www.eff.org/files/2016/07/18/eff_large_wordlist.txt

https://www.eff.org/files/2016/09/08/eff_short_wordlist_1.txt

RAINBOW TABLES

Rainbow Tables are for the most part obsolete but provided here for reference

<http://project-rainbowcrack.com/table.htm>

WORDLIST GENERATION

JOHN THE RIPPER

Generate wordlist that meets complexity specified in the complex filter.

```
john --wordlist=dict.txt --stdout --external : [filter name] > outfile.txt
```

STEMMING PROCESS

Stripping characters from a password list to reach the “stem” or base word/words of the candidate password. Commands are from “File Manipulation Cheat Sheet”.

Extract all lowercase strings from each line and output to wordlist.

```
sed 's/[^\w]*//g' passwords.txt > outfile.txt
```

Extract all uppercase strings from each line and output to wordlist.

```
sed 's/[^A-Z]*//g' passwords.txt > outfile.txt
```

Extract all lowercase/uppercase strings from each line and output to wordlist.

```
sed 's/[^\w]*//g' passwords.txt > outfile.txt
```

Extract all digits from each line in file and output to wordlist.

```
sed 's/[^0-9]*//g' passwords.txt > outfile.txt
```

HASHCAT UTILS

https://hashcat.net/wiki/doku.php?id=hashcat_utils

COMBINATOR

Combine multiple wordlists with each word appended to the other.

```
combinator.bin dict1.txt dict2.txt > combined_dict.txt
```

```
combinator3.bin dict1.txt dict2.txt dict3.txt > combined_dict.txt
```

CUTB

Cut the specific length off the existing wordlist and pass it to STDOUT.

cutb.bin offset [length] < infile.txt > outfile.txt

Example to cut first 4 characters in a wordlist and place into a file:

cutb.bin 0 4 < dict.txt > outfile.txt

RLI

Compares a file against another file or files and removes all duplicates.

rli dict1.txt outfile.txt dict2.txt

REQ

Dictionary candidates are passed to stdout if it matches an specified password group criteria/requirement. Groups can be added together (i.e. 1 + 2 = 3)

1 = LOWER (abcdefghijklmnopqrstuvwxyz)

2 = UPPER (ABCDEFGHIJKLMNOPQRSTUVWXYZ)

4 = DIGIT (0123456789)

8 = OTHER (All other characters not matching 1,2, or 4)

This example would stdout all candidates matching upper and lower characters

req.bin 3 < dict.txt

COMBIPOW

Creates “unique combinations” of a custom dictionary; dictionary cannot be greater than 64 lines; option -1 limits candidates to 15 characters.

combipow.bin dict.txt

combipow.bin -1 dict.txt

EXPANDER

Dictionary into stdin is parsed and split into all its single chars (up to 4) and sent to stdout.

expander.bin < dict.txt

LEN

Each candidate in a dictionary is checked for length and sent to stdout.

len.bin <min len> <max len> < dict.txt

This example would send to stdout all candidates 5 to 10 chars long.

```
len.bin 5 10 < dict.txt
```

MORPH

Auto generates insertion rules for the most frequent chains of characters

```
morph.bin dict.txt depth width pos_min pos_max
```

PERMUTE

Dictionary into stdin parsed and run through “The Countdown QuickPerm Algorithm”

```
permute.bin < dict.txt
```

CRUNCH

Wordlist generator can specify a character set and generate all possible combinations and permutations.

<https://sourceforge.net/projects/crunch-wordlist/>

```
crunch <min length> <max length> <character set> -o outfile.txt
```

```
crunch 8 8 0123456789ABCDEF -o crunch_wordlist.txt
```

TARGETED WORDLISTS

CeWL

Custom wordlist generator scrapes & compiles keywords from websites.

<https://digi.ninja/projects/cewl.php>

Example scan depth of 2 and minimum word length of 5 output to wordlist.txt

```
cewl -d 2 -m 5 -w wordlist.txt http://<target website>
```

SMEEGESCAPE

Text file and website scraper which generates custom wordlists from content.

<http://www.smeegesec.com/2014/01/smeegescrape-text-scraper-and-custom.html>

Compile unique keywords from text file and output into wordlist.

Smeegescrape.py -f file.txt -o wordlist.txt

Scrape keywords from target website and output into wordlist.

Smeegescrape.py -u http://<target website> -si -o wordlist.txt

GENERATE PASSWORD HASHES

Use the below methods to generate hashes for specific algorithms.

HASHCAT

<https://github.com/hashcat/hashcat/tree/master/tools>

test.pl passthrough <#type> <#> dict.txt

MDXFIND

<https://hashes.org/mdxfind.php>

echo | mdxfind -z -h '<#type>' dict.txt

LYRICPASS (Song Lyrics Password Generator)

<https://github.com/initstring/lyricpass>

Generator using song lyrics from chosen artist to create custom dictionary.

python lyricpass.py "Artist Name" artist-dict.txt

CONVERT WORDLIST ENCODING

HASHCAT

Force internal wordlist encoding from X

hashcat -a 0 -m #type hash.txt dict.txt --encoding-from=utf-8

Force internal wordlist encoding to X

```
hashcat -a 0 -m #type hash.txt dict.txt --encoding-to=iso-8859-15
```

ICONV

Convert wordlist into language specific encoding

```
iconv -f <old_encode> -t <new_encode> < dict.txt | sponge dict.txt.enc
```

CONVERT HASHCAT \$HEX OUTPUT

Example of converting \$HEX[] entries in hashcat.potfile to ASCII

```
grep '$HEX' hashcat.pot | awk -F ":" '{print $2}' | perl -ne 'if ($_ =~ m/^$HEX\\([A-Fa-f0-9]+)\\)/ {print pack ("H*", $1), "\n"}'
```

EXAMPLE CUSTOM DICTIONARY CREATION

1-Create a custom dictionary using CeWL from www.netmux.com website:

```
cewl -d 2 -m 5 -w custom_dict.txt http://www.netmux.com
```

2-Combine the new custom_dict.txt with the Google 10,000 most common English words: <https://github.com/first20hours/google-10000-english>

```
cat google-1000.txt >> custom_dict.txt
```

3-Combine with Top 196 passwords from “Probable Wordlists”:

```
github.com/berzerk0/Probable-Wordlists/blob/master/Real-Passwords
```

```
cat Top196-probable.txt >> custom_dict.txt
```

4-Combo the Top196-probable.txt together using Hashcat-util “combinator.bin” and add it to our custom_dict.txt

```
combinator.bin Top196-probable.txt Top196-probable.txt >> custom_dict.txt
```

5-Run the best64.rule from Hashcat on Top196-probable.txt and send that output

into our custom dictionary:

```
hashcat -a 0 Top196-probable.txt -r best64.rule --stdout >> custom_dict.txt
```

Can you now come up with an attack that can crack this hash?

e4821dl6a298092638ddb7cadc26d32f

**Answer in the Appendix*

RULES & MASKS

RULES & MASKS

RULE FUNCTIONS

Following are compatible between Hashcat, John The Ripper, & PasswordPro

https://hashcat.net/wiki/doku.php?id=rule_based_attack

NAME	FUNCTION	DESCRIPTION
Nothing	:	Do nothing
Lowercase	l	Lowercase all letters
Uppercase	u	Uppercase all letters
Capitalize	c	Capitalize the first letter and lower the rest
Invert Capitalize	C	Lowercase first character, uppercase rest
Toggle Case	t	Toggle the case of all characters in word.
Toggle @	TN	Toggle the case of characters at position N
Reverse	r	Reverse the entire word
Duplicate	d	Duplicate entire word
Duplicate N	pN	Append duplicated word N times
Reflect	f	Duplicate word reversed
Rotate Left	{	Rotates the word left.
Rotate Right	}	Rotates the word right
AppendChar	\$X	Append character X to end
PrependChar	^X	Prepend character X to front
Truncate left	[Deletes first character
Truncate right]	Deletes last character
Delete @ N	DN	Deletes character at position N
Extract range	xNM	Extracts M characters, starting at position N
Omit range	ONM	Deletes M characters, starting at position N
Insert @ N	iNX	Inserts character X at position N
Overwrite @ N	oNX	Overwrites character at position N with X
Truncate @ N	'N	Truncate word at position N
Replace	sXY	Replace all instances of X with Y
Purge	@X	Purge all instances of X
Duplicate first N	zN	Duplicates first character N times
Duplicate last N	ZN	Duplicates last character N times
Duplicate all	q	Duplicate every character
Extract memory	XNMI	Insert substring of length M starting at position N of word in memory at position I
Append memory	4	Append word in memory to current word
Prepend memory	6	Prepend word in memory to current word
Memorize	M	Memorize current word

RULES TO REJECT PLAINS

https://hashcat.net/wiki/doku.php?id=rule_based_attack

NAME	FUNCTION	DESCRIPTION
Reject less	<N	Reject plains of length greater than N
Reject greater	>N	Reject plains of length less than N
Reject contain	!X	Reject plains which contain char X
Reject not contain	/X	Reject plains which do not contain char X
Reject equal first	(X	Reject plains which do not start with X
Reject equal last)X	Reject plains which do not end with X
Reject equal at	=NX	Reject plains which do not have char X at position N
Reject contains	%NX	Reject plains which contain char X less than N times
Reject contains	Q	Reject plains where the memory saved matches current word

IMPLEMENTED SPECIFIC FUNCTIONS

Following functions are not compatible with John The Ripper & PasswordPro

NAME	FUNCTION	DESCRIPTION
Swap front	k	Swaps first two characters
Swap back	K	Swaps last two characters
Swap @ N	*XY	Swaps character X with Y
Bitwise shift left	LN	Bitwise shift left character @ N
Bitwise shift right	RN	Bitwise shift right character @ N
Ascii increment	+N	Increment character @ N by 1 ascii value
Ascii decrement	-N	Decrement character @ N by 1 ascii value
Replace N + 1	.N	Replaces character @ N with value at @ N plus 1
Replace N - 1	,N	Replaces character @ N with value at @ N minus 1
Duplicate block front	yN	Duplicates first N characters
Duplicate block back	YN	Duplicates last N characters
Upper Lower	E	Lower case the whole line, then upper case the first letter and every letter after a space

RULE ATTACK CREATION

EXAMPLE RULE CREATION & OUTPUT

Below we apply basic rules to help explain the expected output when using rules.

<u>WORD</u>	<u>RULE</u>	<u>OUTPUT</u>
password	\$1	password1
password	^!^1	1!password
password	so0 sa@	p@ssw0rd
password	c so0 sa@ \$1	P@ssw0rd1
password	u r	DROWSSAP

MASKPROCESSOR HASHCAT-UTIL

<https://github.com/hashcat/maskprocessor>

Maskprocessor can be used to generate a long list of rules very quickly.

Example rule creation of prepend digit and special char to dictionary candidates (i.e. ^1^! , ^2^@ , ...) :

```
mp64.bin '^?d ^?s' -o rule.txt
```

Example creating rule with custom charset appending lower, uppercase chars and all digits to dictionary candidates (i.e. \$a \$Q \$1 , \$e \$A \$2, ...) :

```
mp64.bin -1 aeiou -2 QAZWSX '$?1 $?2 $?d'
```

GENERATE RANDOM RULES ATTACK (i.e. “Raking”)

```
hashcat -a 0 -m #type -g <#rules> hash.txt dict.txt
```

GENERATE RANDOM RULES FILE USING HASHCAT-UTIL

```
generate-rules.bin <#rules> <seed> | ./cleanup-rules.bin [1=CPU,2=GPU] > out.txt
```

```
generate-rules.bin 1000 42 | ./cleanup-rules.bin 2 > out.txt
```

SAVE SUCCESSFUL RULES/METRICS

```
hashcat -a 0 -m #type --debug-mode=l --debug-file=debug.txt hash.txt -r rule.txt
```

SEND RULE OUTPUT TO STDOUT / VISUALLY VERIFY RULE OUTPUT

```
hashcat dict.txt -r rule.txt --stdout
```

```
john --wordlist=dict.txt --rules=example --stdout
```

PACK (Password Analysis and Cracking Kit) RULE CREATION

<http://thesprawl.org/projects/pack/>

RULEGEN

Advanced techniques for reversing source words and word mangling rules from already cracked passwords by continuously recycling/expanding generated rules and words. Outputs rules in Hashcat format.

<http://thesprawl.org/research/automatic-password-rule-analysis-generation/>

Ensure you install ‘AppleSpell’ ‘aspell* module using packet manager

```
python rulegen.py --verbose --password P@ssw0rdl23
```

RULEGEN OPTIONS

-b rockyou

Output base name. The following files will be generated: basename.words, basename.rules and basename.stats

-w wiki.dict

Use a custom wordlist for rule analysis.

-q, --quiet

Don’t show headers.

--threads=THREADS

Parallel threads to use for processing.

Fine tune source word generation::

--maxworddist=10

Maximum word edit distance (Levenshtein)

--maxwords=5

Maximum number of source word candidates to consider

--morewords

Consider suboptimal source word candidates

--simplewords

Generate simple source words for given passwords

Fine tune rule generation::

--maxrulelen=10

Maximum number of operations in a single rule

--maxrules=5

Maximum number of rules to consider

--morerules

Generate suboptimal rules

--simplerules Generate simple rules insert,delete,replace
--bruterules Bruteforce reversal and rotation rules (slow)

Fine tune spell checker engine::

--providers=aspell,myspell Comma-separated list of provider engines

Debugging options::

-v, --verbose	Show verbose information.
-d, --debug	Debug rules.
--password	Process the last argument as a password not a file.
--word=Password	Use a custom word for rule analysis
--hashcat	Test generated rules with hashcat-cli

RULEGEN EXAMPLES

Analysis of a single password to automatically detect rules and potential source word used to generate a sample password:

python rulegen.py --verbose --password P@ssw0rdl23

Analyze passwords.txt and output results:

python rulegen.py passwords.txt -q

analysis.word - unsorted and non-uniqued source words
analysis-sorted.word - occurrence sorted and unique source words
analysis.rule - unsorted and non-uniqued rules
analysis-sorted.rule - occurrence sorted and unique rules

MASK ATTACK CREATION

DEBUG / VERIFY MASK OUTPUT

```
hashcat -a 3 ?a?a?a?a --stdout
john --mask=?a?a?a?a --stdout
```

HASHCAT MASK ATTACK CREATION

Example usage:

```
hashcat -a 3 -m #type hash.txt <mask>
```

Example brute-force all possible combinations 7 characters long:

```
hashcat -a 3 -m #type hash.txt ?a?a?a?a?a?a?a
```

Example brute-force all possible combinations 1 - 7 characters long:

```
hashcat -a 3 -m #type hash.txt -i ?a?a?a?a?a?a?a
```

Example brute-force uppercase first letter, 3 unknown middle characters, and ends in 2 digits (i.e. Pass12):

```
hashcat -a 3 -m #type hash.txt ?u?a?a?a?d?d
```

Example brute-force known first half word “secret” and unknown ending:
hashcat -a 3 -m #type hash.txt secret?a?a?a?a

Example hybrid mask (leftside) + wordlist (rightside) (i.e. 123!Password)
hashcat -a 7 -m #type hash.txt ?a?a?a?a dict.txt

Example wordlist (leftside) + hybrid mask (rightside) (i.e. Password123!)
hashcat -a 6 -m #type hash.txt dict.txt ?a?a?a?a

HASHCAT CUSTOM CHARSETS

Four custom buffer charsets to create efficient targeted mask attacks defined as: **-1 -2 -3 -4**

Example custom charset targeting passwords that only begin in a,A,b,B,or c,C , 4 unknown middle characters, and end with a digit (i.e. al7z#q7): hashcat -a 3 -m #type hash.txt -1 abcABC ?l?a?a?a?a?d

Example custom charset targeting passwords that only begin in uppercase or lowercase, 4 digits in the middle, and end in special character !,@,\$ (i.e. W7462! or f1234\$):

```
hashcat -a 3 -m #type hash.txt -1 ?u?l -2 !@$ ?l?d?d?d?d?2
```

Example using all four custom charsets at once (i.e. pow!12er):

```
hashcat -a 3 -m #type hash.txt -1 qwer -2 poi -3 123456 -4 !@#$% ?2?2?1?4?3?3?  
1?1
```

JOHN MASK ATTACK CREATION

Example usage:

```
john --format=#type hash.txt --mask=<mask>
```

Example brute-force all possible combinations up to 7 characters long:

```
john --format=#type hash.txt --mask=?a?a?a?a?a?a?a
```

Example brute-force uppercase first letter, 3 unknown middle characters, and ends in 2 digits (i.e. PassI2):

```
john --format=#type hash.txt --mask=?u?a?a?a?d?d
```

Example brute-force known first half word “secret” and unknown ending:

```
john --format=#type hash.txt --mask=secret?a?a?a?a
```

Example mask (leftside) + wordlist (rightside) (i.e. 123!Password)

john --format=#type hash.txt --wordlist=dict.txt --mask=?a?a?a?a?w

Example wordlist (leftside) + mask (rightside) (i.e. Password123!)

john --format=#type hash.txt --wordlist=dict.txt --mask=?w?a?a?a?a

JOHN CUSTOM CHARSETS

Nine custom buffer charsets to create efficient targeted mask attacks defined as: **-1 -2 -3 -4 -5 -6 -7 -8 -9**

Example custom charset targeting passwords that only begin in a,A,b,B,or c,C , 4 unknown middle characters, and end with a digit (i.e. a17z#q7):

john --format=#type hash.txt -1=abcABC --mask=?l?a?a?a?a?d

Example custom charset targeting passwords that only begin in uppercase or lowercase, 4 digits in the middle, and end in special character !,@,\$ (i.e. W7462! or f1234\$):

john --format=#type hash.txt -1=?u?l -2=!@\$ --mask=?l?d?d?d?d?2

Example using four custom charsets at once (i.e. pow!12er):

john --format=#type hash.txt -1=qwer -2=poiu -3=123456 -4=!@#\$%, --mask=?2??2?l?4? 3?3?1?1

HASHCAT MASK CHEAT SHEET

?l = lowercase = 26 chars = abcdefghijklmnopqrstuvwxyz

?u = uppercase = 26 chars = ABCDEFGHIJKLMNOPQRSTUVWXYZ

?d = digits = 10 chars = 0123456789

?s = special = 33 chars = «space»!"#\$%&'()*+,./:;=>?@[\\]^_`{|}~

?a = all = 95 chars = lowercase+uppercase+digits+special

?h = hex = 16 chars = 0123456789abcdef

?H = HEX = 16 chars = 0123456789ABCDEF

?b = byte = 256 byte = 0x00 - 0xff

JOHN MASK CHEAT SHEET

```

?l = lowercase      = 26 chars = abcdefghijklmnopqrstuvwxyz
?u = uppercase      = 26 chars = ABCDEFGHIJKLMNOPQRSTUVWXYZ
?d = digits         = 10 chars = 0123456789
?s = special        = 33 chars = «space»!"#$%&'()*+,.-./:;<=>?@[\\]^_`{|}~
?a = all            = 95 chars = lowercase+uppercase+digits+special
?h = hex             0x80 - 0xff
?A = all valid characters in the current code page
?h = all 8-bit (0x80-0xff)
?H = all except the NULL character
?L = non-ASCII lower-case letters
?U = non-ASCII upper-case letters
?D = non-ASCII "digits"
?S = non-ASCII "specials"
?w = Hybrid mask mode placeholder for the original word

```

MASK FILES

Hashcat allows for the creation of mask files by placing custom masks, one per line, in a text file with “.hcmask” extension.

HASHCAT BUILT-IN MASK FILES	Approx # Masks
8char-11-1u-1d-1s-compliant.hcmask	40,824
8char-11-1u-1d-1s-noncompliant.hcmask	24,712
rockyou-1-60.hcmask	836
rockyou-2-1800.hcmask	2,968
rockyou-3-3600.hcmask	3,971
rockyou-4-43200.hcmask	7,735
rockyou-5-86400.hcmask	10,613
rockyou-6-864000.hcmask	17,437
rockyou-7-2592000.hcmask	25,043

PACK (Password Analysis and Cracking Kit) MASK CREATION

<http://thesprawl.org/projects/pack/>

MASKGEN

MaskGen allows you to automatically generate pattern-based mask attacks from

known passwords and filter by length and desired cracking time.

python maskgen.py example.mask

MASKGEN OPTIONS

```
-t                      target cracking time of all masks combined (seconds)
-o <file.hcmask>        output masks to a file
--showmasks            show matching masks
```

Individual Mask Filter Options:

```
--minlength=8          Minimum password length
--maxlength=8          Maximum password length
--mintime=3600          Minimum mask runtime (seconds)
--maxtime=3600          Maximum mask runtime (seconds)
--mincomplexity=1       Minimum complexity
--maxcomplexity=100     Maximum complexity
--minoccurrence=1       Minimum occurrence
--maxoccurrence=100     Maximum occurrence
```

Mask Sorting Options:

```
--optindex              sort by mask optindex (default)
--occurrence            sort by mask occurrence
--complexity            sort by mask complexity
```

Check mask coverage:

```
--checkmasks=?u?1?1?1?1?1?d,?1?1?1?1?1?d?d      check mask coverage
--checkmasksfile=masks.hcmask                         check mask coverage in a file
```

Miscellaneous options:

```
--pps=1000000000          Passwords per Second
```

MASKGEN EXAMPLES

Gather stats about cracked passwords.txt and hide the less than 1% results:

```
python statsgen.py --hiderare passwords.txt
```

Save masks stats to a .mask file for further analysis:

```
python statsgen.py --hiderare passwords.txt -o example.mask
```

Analyze example.mask results, number of masks, estimated time to crack, etc...

```
python maskgen.py example.mask
```

**Create 24 hour (86400 seconds) mask attack based on cracking speed of a single
GTX 1080 against MD5 hashes 24943.1 MH/s(based on appendix table).**

!Substitute your GPU's cracking speed against MD5 (c/s)!.

```
python maskgen.py example.mask --targettime=86400 --optindex --
```

pps=24943000000 -q

Output 24 hour mask attack to a .hcmask file for use in Hashcat:

python maskgen.py example.mask --targettime=86400 --optindex --
pps=24943000000 -q -o example.hcmask

Use your new example.hcmask file with Hashcat in mask attack mode:

hashcat -a 3 -m #type hash.txt example.hcmask

TIME TABLE CHEAT SHEET

60 seconds	1 minute
3,600 seconds	1 hour
86,400 seconds	1 day
604,800 seconds	1 week
1,209,600 seconds	1 fortnight
2,419,200 seconds	1 month (30days)
31,536,000 seconds	1 year

POLICYGEN

Generate a collection of masks following the password complexity in order to significantly reduce the cracking time.

python policygen.py [options] -o example.hcmask

POLICYGEN OPTIONS

-o masks.hcmask	Save masks to a file
--pps=1000000000	Passwords per Second
--showmasks	Show matching masks
--noncompliant	Generate masks for noncompliant passwords
-q, --quiet	Don't show headers.

Password Policy:

Define the minimum (or maximum) password strength policy that you would like to test

```
--minlength=8      Minimum password length
--maxlength=8      Maximum password length
--mindigit=1       Minimum number of digits
--minlower=1        Minimum number of lower-case characters
--minupper=1        Minimum number of upper-case characters
--minspecial=1     Minimum number of special characters
--maxdigit=3        Maximum number of digits
--maxlower=3        Maximum number of lower-case characters
--maxupper=3        Maximum number of upper-case characters
--maxspecial=3     Maximum number of special characters
```

POLICYGEN EXAMPLES

Generate mask attack for password policy 8 character length requiring at least 1 lowercase, 1 uppercase, 1 digit, and 1 special character:

```
python policygen.py --minlength 8 --maxlength 8 --minlower 1 --minupper 1 --
mindigit 1 --minspecial 1 -o example.hcmask
```

Generate mask attack and estimate time of completion based on GTX 1080 against MD5 hashes 24943.1 MH/s(based on appendix table) for password policy 8 character length requiring at least 1 lowercase, 1 uppercase, 1 digit, and 1 special character:

```
python policygen.py --minlength 8 --maxlength 8 --minlower 1 --minupper 1 --
mindigit 1 --minspecial 1 -o example.hcmask --pps=24943000000
```

CUSTOM MASK PLANS

DATE YYMMDD MASK

```
hashcat -a 3 -m #type hash.txt -1 12 -2 90 -3 01 -4 123 ?l?2?3?d?4?d
```

DATE YYYYMMDD MASK

```
hashcat -a 3 -m #type hash.txt -1 12 -2 90 -3 01 -4 123 ?l?2?d?d?3?d? 4?d
```

3 SEQUENTIAL NUMBERS MASK + SPECIAL

```
hashcat -a 3 -m #type hash.txt -1 147 -2 258 -3 369 ?l?2?3?s
```

FOREIGN CHARACTER SETS

HASHCAT BUILT-IN CHARSETS

German

hashcat -a 3 -m #type hash.txt -1 charsets/German.hcchr -i ?1?1?1?1

French

hashcat -a 3 -m #type hash.txt -1 charsets/French.hcchr -i ?1?1?1?1

Portuguese

hashcat -a 3 -m #type hash.txt -1 charsets/Portuguese.hcchr -i ?1?1?1?1

SUPPORTED LANGUAGE ENCODINGS

hashcat -a 3 -m #type hash.txt -1 charsets/<language>.hcchr -i ?1?1?1?1

Bulgarian, Castilian, Catalan, English, French, German, Greek, Greek Polytonic, Italian, Lithuanian, Polish, Portuguese, Russian, Slovak, Spanish

JOHN UTF8 & BUILT-IN CHARSETS

OPTIONS:

--encoding=NAME	input encoding (eg. UTF-8, ISO- 8859-1).
--input-encoding=NAME	input encoding (alias for --encoding)
--internal-encoding=NAME	encoding used in rules/masks (see doc/ENCODING)
- -target-encoding=NAME	output encoding (used by format)

Example LM hashes from Western Europe, using a UTF-8 wordlist:

john --format=lm hast.txt --encoding=utf8 --target:cp850 --wo:spanish.txt

Example using UTF-8 wordlist with internal encoding for rules processing:

john --format=#type hash.txt --encoding=utf8 --internal=CP1252 --wordlist=french.1st --rules

Example mask mode printing all possible “Latin-1” words of length 4:
john --stdout --encoding=utf8 --internal=8859-1 --mask:?1?1?1?1

SUPPORTED LANGUAGE ENCODINGS

UTF-8, ISO-8859-1 (Latin), ISO-8859-2 (Central/Eastern Europe), ISO-8859-7 (Latin/Greek), ISO-8859-15 (Western Europe), CP437 (Latin), CP737 (Greek), CP850 (Western Europe), CP852 (Central Europe), CP858 (Western Europe), CP866 (Cyrillic), CP1250 (Central Europe), CP1251 (Russian), CP1252 (Default Latin1), CP1253 (Greek) and KOI8-R (Cyrillic).

HASHCAT ?b BYTE CHARSET

If you’re unsure as to position of a foreign character set contained within your target password, you can attempt the ?b byte charset in a mask using a sliding window. For example if we have a password 6 characters long:

?b = 256 byte = 0x00 - 0xff

hashcat -a 3 -m #type hash.txt

?b?a?a?a?a?
?a?b?a?a?a?
?a?a?b?a?a?
?a?a?a?b?a?
?a?a?a?a?b?
?a?a?a?a?a?

CONVERT ENCODING

HASHCAT

Force internal wordlist encoding from X

hashcat -a 0 -m #type hash.txt dict.txt --encoding-from=utf-8

Force internal wordlist encoding to X

hashcat -a 0 -m #type hash.txt dict.txt --encoding-to=iso-8859-15

ICONV

Convert wordlist into language specific encoding

iconv -f <old_encode> -t <new_encode> <dict.txt| sponge dict.txt.enc

CONVERT HASHCAT \$HEX OUTPUT

Example of converting \$HEX[] entries in hashcat.pot file to ASCII

```
grep '$HEX' hashcat.pot | awk -F ":" {print$2} |perl -ne 'if($_ =~ m/^$HEX\\([A-Fa-f0-9]+)\\]/){print pack("H*", $1), "\n"}'
```

ADVANCED ATTACKS

ADVANCED ATTACKS

PRINCE ATTACK

PRINCE (PRobability INfinite Chained Elements) Attack takes one input wordlist and builds “chains” of combined words automatically.

HASHCAT PRINCEPROCESSOR

<https://github.com/hashcat/princeprocessor>

Attack slow hashes:

```
pp64.bin dict.txt | hashcat -a 0 -m #type hash.txt
```

Amplified attack for fast hashes:

```
pp64.bin --case-permute dict.txt | hashcat -a 0 -m #type hash.txt -r rule.txt
```

Example PRINCE attack producing minimum 8 char candidates with 4 elements piped directly into Hashcat with rules attack.

```
pp64.bin --pw-min=8 --limit=4 dict.txt|hashcat -a 0 -m # hash.txt -r best64.rule
```

PRINCECEPTION ATTACK (epixoip)

Piping the output of one PRINCE attack into another PRINCE attack.

```
pp64.bin dict.txt | pp64.bin | hashcat -a 0 -m #type hash.txt
```

JOHN BUILT-IN PRINCE ATTACK

```
john --prince=dict.txt hash.txt
```

MASK PROCESSOR

Mask attack generator with a custom configurable charset and ability to limit consecutive and repeating characters to decrease attack keyspace.

<https://github.com/hashcat/maskprocessor>

Limit 4 consecutive identical characters in the password string “-q” option:

```
mp64.bin -q 4 ?d?d?d?d?d?d?d | hashcat -a 0 -m #type hash.txt
```

Limit 4 identical characters in the password string “-r” option:

```
mp64.bin -r 4 ?d?d?d?d?d?d?d | hashcat -a 0 -m #type hash.txt
```

Limit 2 consecutive and 2 identical characters in the password string:

```
mp64.bin -r 2 -q 2 ?d?d?d?d?d?d?d | hashcat -a 0 -m #type hash.txt
```

Custom charset limiting 2 consecutive and 2 identical characters in the password string:

```
mp64.bin -r 2 -q 2 -1 aeiuo -2 TGBYHN ?l?2?l?2?d?d?d?d | hashcat -a 0 -m #type hash.txt
```

CUSTOM MARKOV MODEL / STATSPROCESSOR

Word-generator based on the per-position markov-attack.

<https://github.com/hashcat/statsprocessor>

HCSTATGEN

Create custom Markov models using hashcat-util hcstatgen.bin based on cracked target passwords. The util hcstatgen makes a 32MB file each time no matter how small/large the password list provided. Highly recommended you make custom Markov models for different target sets.

```
hcstatgen.bin outfile.hcstat < passwords.txt
```

STATSPROCESSOR

Is a high-performance word-generator based on a user supplied per-position Markov

model (hcstat file) using mask attack notation.

Step 1: Create your custom Markov model

```
hcstatgen.bin out.hcstat < passwords.txt
```

Step 2.1: Supply your new Markov model to Hashcat as mask or rule attack.

```
hashcat -a 3 -m #type hash.txt --markov-hcstat=out.hcstat ?a?a?a?a?a?a
```

```
hashcat -a 0 -m #type hash.txt dict.txt -r rule.txt --markov-hcstat=out.hcstat
```

Step 2.2: OR Supply your new Markov model with sp64 and pipe into Hashcat.

```
sp64.bin --pw-min 3 --pw-max 5 out.hcstat ?1?1?1?1?1?1 | hashcat -a 0 -m #type hash.txt
```

KEYBOARD WALK PROCESSOR

Keyboard-walk generator with configurable base chars, keymappings and routes.
<https://github.com/hasheat/kwprocessor>

Example keyboard walk with tiny charset in english mapping and with 2-10 adjacent keys piping out results into a hashcat attack:

```
kwp.bin basechar/tiny.base keymaps/en.keymap routes/2-to-10-max-3 -0 -z |  
hashcat -a 0 -m #type hash.txt
```

Example keyboard walk with full charset in english mapping and with 3x3 adjacent keys piping out results into a hashcat attack:

```
./kwp basechars/full.base keymaps/en.keymap routes/3-to-3-exhaustive.route |  
hashcat -a 0 -m #type hash.txt
```

[FULL LIST OF OPTIONS]

```
./kwp [options]... basechars-file keymap-file routes-file  
-V, --version          Print version  
-h, --help              Print help  
-o, --output-file      Output-file  
-b, --keyboard-basic   Characters reachable without holding shift or altgr  
-s, --keyboard-shift   Characters reachable by holding shift  
-a, --keyboard-altgr   Characters reachable by holding altgr (non-english)  
-z, --keyboard-all     Shortcut to enable all --keyboard-* modifier  
-1, --keywalk-south-west Routes heading diagonale south-west  
-2, --keywalk-south    Routes heading straight south  
-3, --keywalk-south-east Routes heading diagonale south-east  
-4, --keywalk-west     Routes heading straight west  
-5, --keywalk-repeat   Routes repeating character  
-6, --keywalk-east     Routes heading straight east  
-7, --keywalk-north-west Routes heading diagonale north-wes  
-8, --keywalk-north    Routes heading straight north  
-9, --keywalk-north-east Routes heading diagonale north-east  
-0, --keywalk-all      Shortcut to enable all --keywalk-* directions  
-n, --keywalk-distance-min Minimum allowed distance between keys  
-x, --keywalk-distance-max Maximum allowed distance between keys
```

MDXFIND / MDSPLIT

<https://hashes.org/mdxfind.php>

(credit ‘Waffle’)

MDXFIND is a program which allows you to run large numbers of unsolved hashes of any type, using many algorithms concurrently, against a large number of plaintext words and rules, very quickly. Its main purpose was to deal with large lists (20 million, 50 million, etc) of unsolved hashes and run them against new dictionaries as you acquire them.

So when would you use MDXFIND on a pentest? If you dump a database tied to website authentication and the hashes are not cracking by standard attack plans. The hashes may be generated in a unique nested hashing series. If you are able to view the source code of said website to view the custom hashing function you can direct MDXFIND to replicate that hashing series. If not, you can still run MDXFIND using some of the below ‘Generic Attack Commands’. MDXFIND is tailored toward intermediate to expert level password cracking but is extremely powerful and flexible.

Example website SHA1 custom hashing function performing multiple iterations:

```
$hash = sha1($password . $salt);
for ($i = 1; $i <= 65000; ++$i)
{
    $hash = sha1($hash . $salt);
}
```

MDXFIND

COMMAND STRUCTURE THREE METHODS **1-STDOUT 2-STDIN 3-File**

1- Reads hashes coming from cat (or other) commands stdout.

```
cat hash.txt | mdxfind -h <regex #type> -i <#iterations> dict.txt > out.txt
```

2- Takes stdin from outside attack sources in place of dict.txt when using the options variable ‘-f’ to specify hash.txt file location and variable ‘stdin’.

```
mp64.bin ?d?d?d?d?d | mdxfind -h <regex #type> -i <#iterations> -f hash.txt
stdin > out.txt
```

3- Specify file location ‘-f’ with no external stdout/stdin sources.

```
mdxfind -h <regex #type> -i <#iterations> -f hash.txt dict.txt > out.txt
```

[FULL LIST OF OPTIONS]

- a Do email address munging
- b Expand each word into unicode, best effort
- c Replace each special char (<>&, etc) with XML equivalents
- d De-duplicate wordlists, best effort...but best to do ahead of time
- e Extended search for truncated hashes
- p Print source (filename) of found plain-texts
- Internal iteration counts for SHA1MD5X, and others. For example, if you have a hash that is SHA1(MD5(MD5(MD5(MD5(\$pass))))), you would set -q to 5.
- g Rotate calculated hashes to attempt match to input hash
- s File to read salts from
- u File to read Userid/Usernames from
- k File to read suffixes from
- Number of digits to append to passwords. Other options, like: -n 6x would append 6 digit hex values, and 8i would append all ipv4 dotted-quad IP-addresses.
- i The number of iterations for each hash
- t The number of threads to run
- f file to read hashes from, else stdin
- l Append CR/LF/CRLF and print in hex
- r File to read rules from
- v Do not mark salts as found.
- w Number of lines to skip from first wordlist
- y Enable directory recursion for wordlists
- z Enable debugging information/hash results
- h The hash types: 459 TOTAL HASHES SUPPORTED

GENERIC ATTACK PLANS

This is a good general purpose MDXFIND command to run your hashes against if you suspect them to be “non-standard” nested hashing sequences. This command says “Run all hashes against dict.txt using 10 iterations except ones having a salt, user, or md5x value in the name.” It’s smart to skip salted/user hash types in MDXFIND unless you are confident a salt value has been used.

```
cat hash.txt | mdxfind -h ALL -h '!salt,!user,!md5x' -i 10 dict.txt > out.txt
```

The developer of MDXFIND also recommends running the below command options as a good general purpose attack:

```
cat hash.txt | mdxfind -h <^md5$,^sha1$,^md5md5pass$,^md5sha1$' -i 5  
dict.txt > out.txt
```

And you could add a rule attack as well:

```
cat hash.txt | mdxfind -h <^md5$,^sha1$,^md5md5pass$,^md5sha1$' -i 5  
dict.txt -r best64.rule > out.txt
```

GENERAL NOTES ABOUT MDXFIND

-Can do multiple hash types/files all during a single attack run.

```
cat sha1/*.txt sha256/*.txt md5/*.txt salted/*.txt | mdxfind
```

-Supports 459 different hash types/sequences

-Can take input from special 'stdin' mode

-Supports VERY large hashlists (100mil) and 10kb character passwords

-Supports using hashcat rule files to integrate with dictionary

-Option '-z' outputs ALL viable hashing solutions and file can grow very large

-Supports including/excluding hash types by using simple regex parameters

-Supports multiple iterations (up to 4 billion times) by tweaking -i parameter for instance:

MD5X01 is the same as md5(\$Pass)

MD5x02 is the same as md5(md5(\$pass))

MD5X03 is the same as md5(md5(md5(\$pass)))

...

MD5x10 is the same as

md5(md5(md5(md5(md5(md5(md5(md5(md5(\$pass))))))))))

-Separate out -usernames -email -ids -salts to create custom attacks

-If you are doing brute-force attacks, then hashcat is probably better route

-When MDXfind finds any solution, it outputs the kind of solution found, followed by the hash, followed by the salt and/or password. For example:

Solution	HASH	:PASSWORD
----------	------	-----------

MD5X01 000012273bc5cab48bf3852658b259ef:lEb0TBK3

MD5X05 033blll073e5f64ee59f0be9d6b8a561:08061999

MD5X09 aadb9dlb23729a3e403d7fc62d507df7:1140

MD5X09 326d921d591162eed302ee25a09450ca:1761974

MDSPLIT

When cracking large lists of hashes from multiple file locations, MDSPLIT will help match which files the cracked hashes were found in, while also outputting them into separate files based on hash type. Additionally it will remove the found hashes from the original hash file.

COMMAND STRUCTURE TWO METHODS 1-STDOUT 2-STDIN 3-File

1- Matching MDXFIND results files with their original hash_orig.txt files.

```
cat hashes_out/out_results.txt | mdsplit hashes_orig/hash_orig.txt
```

OR perform matching against a directory of original hashes and their results.

```
cat hashes_out/* | mdsplit hashes_orig/*
```

2- Piping MDXFIND directly into MDSPLIT to sort in real-time results.

```
cat *.txt | mdxfind -h ALL -h '!salt,!user,!md5x' -i 10 dict.txt | mdsplit *.txt
```

3- Specifying a file location in MDXFIND to match results in real-time.

```
mdxfind -h ALL -f hashes.txt -i 10 dict.txt | mdsplit hashes.txt
```

GENERAL NOTES ABOUT MDSPLIT

-MDSPLIT will append the final hash solution to the end of the new filename. For example, if we submitted a ‘hashes.txt’ and the solution to the hashes was ‘MD5x01’ then the results file would be ‘hashes.MD5x01’. If multiple hash solutions are found then MDSPLIT knows how to deal with this, and will then remove each of the solutions from hashes.txt, and place them into ‘hashes.MD5x01’, ‘hashes.MD5x02’, ‘hashes.SHA1’... and so on.

-MDSPLIT can handle sorting multiple hash files, types, and their results all at one time. Any solutions will be automatically removed from all of the source files by MDSPLIT, and tabulated into the correct solved files. For example:

```
cat dir1/*.txt dir2/*.txt dir3/*.txt | mdxfind -h '^md5$|^sha1$|^sha256$' -i 10 dict.txt | mdsplit dir1/*.txt dir2/*.txt dir3/*.txt
```

DISTRIBUTED / PARALLELIZATION CRACKING

HASHCAT

<https://hashcat.net/forum/thread-3047.html>

Step 1: Calculate keyspace for attack (Example MD5 Brute Force x 3nodes)

hashcat -a 3 -m 0 ?a?a?a?a?a?a --keyspace

81450625

Step 2: Distribute work through keyspace division (s)kip and (l)imit

81450625 / 3 = 27150208.3

Node1# hashcat -a 3 -m 0 hash.txt ?a?a?a?a?a -s 0 -1 27150208

Node2# hashcat -a 3 -m 0 hash.txt ?a?a?a?a?a -s 27150208 -1 27150208

Node3# hashcat -a 3 -m 0 hash.txt ?a?a?a?a?a -s 54300416 -1 27150209

JOHN

<http://www.openwall.com/john/doc/OPTIONS.shtml>

Manual distribution using Options --node & --fork to 3 similar CPU nodes utilizing 8 cores:

Node# john --format=<#> hash.txt --wordlist=dict.txt --rules=All --fork=8 --node=1-8/24

Node2# john --format=<#> hash.txt --wordlist=dict.txt --rules=All --fork=8 --node=9-16/24

Node3# john --format=<#> hash.txt --wordlist=dict.txt --rules=All --fork=8 --node=17-24/24

Other John Options for parallelization:

Option 1:Enable OpenMP through uncommenting in Makefile

Option 2:Create additional incremental modes in john.conf

Option 3:Utilize built-in MPI parallelization

PASSWORD GUESSING FRAMEWORK

<https://github.com/RUB-SysSec/Password-Guessing-Framework>

<https://www.password-guessing.org/>

Password Guessing Framework is an open source tool to provide an automated and reliable way to compare password guessers. It can help to identify individual strengths and weaknesses of a guesser, it's modes of operation, or even the underlying guessing strategies. Therefore, it gathers information about how many passwords from an input file (password leak) have been cracked in relation to the amount of generated guesses. Subsequent to the guessing process an analysis of the cracked passwords is performed.

OTHER CREATIVE ADVANCED ATTACKS

Random creative password attacks using the power of stdin and stdout. Not implying they're useful but to demonstrate the power of mixing and matching. Go forth and create something useful.

PRINCE-MDXFIND ATTACK

```
pp64.bin dict.txt | mdxfind -h ALL -f hash.txt -i 10 stdin > out.txt
```

HASHCAT-UTIL COMBONATOR PRINCE

```
combinator.bin dict.txt dict.txt | pp64.bin | hashcat -a 0 -m #type hash.txt -r best64.rule
```

```
combinator3.bin dict.txt dict.txt dict.txt | pp64.bin | hashcat -a 0 -m #type hash.txt -r rockyou-30000.rule
```

HASHCAT STDOUT ATTACKS PRINCE

```
hashcat -a 0 dict.txt -r dive.rule --stdout | pp64.bin | hashcat -a 0 -m #type hash.txt
```

```
hashcat -a 6 dict.txt ?a?a?a?a --stdout | pp64.bin --pw-min=8 | hashcat -a 0 -m #type hash.txt
```

```
hashcat -a 7 ?a?a?a?a dict.txt --stdout | pp64.bin --pw-min=8 | hashcat -a 0 -m #type hash.txt
```

```
hashcat -a 6 dict.txt rockyou-1-60.hcmask --stdout | pp64.bin --pw-min=8 --pw-max=14 I hashcat -a 0 -m #type hash.txt
```

```
hashcat -a 7 rockyou-1-60.hcmask dict.txt --stdout | pp64.bin --pw-min=8 --pw-max=14 I hashcat -a 0 -m #type hash.txt
```

CRACKING CONCEPTS

Information in this chapter is an attempt to summarize a few of the basic and more complex concepts in password cracking. This allows all skill levels to grasp these concepts without needing a Linguistics or Mathematics Degree. It's an almost impossible task to condense into one paragraph, but the following is an attempt. For a deeper understanding, I highly encourage you to read the Resource links included below each section.

PASSWORD ENTROPY vs CRACK TIME

Password entropy is a measure of how random/unpredictable a password could have been, so it does not really relate to the password itself, but to a selection process. When judging human generated passwords for entropy, it frankly isn't an accurate measurement. This is true mainly because humans like to use memorable words/sequences and thus a myriad of attacks account for that behavior. However, entropy is good for measuring randomly generated passwords from password managers, such as 1Password or Keepass, in that each default character set used can be calculated. Password entropy is measured in bits and uses the following formula where C=Size of Character set & L=Length of password: $\log(C) / \log(2) * L$. To calculate the time to crack, just use the benchmarking function on your favorite cracking software against your mode of hash to obtain cracks per second. The table below estimates password length using an MD4 hashing function against an 8 GPU x Nvidia GTX1080 system:

Length	Alphanumeric 0-9, a-z, A-Z	Time to Crack (350 GH/s)
8	47 bits	~15 Mins
9	59 bits	
10	65 bits	~457 Hours
11	65 bits	~3.3 Years
12	71 bits	~214 Years
13	77 bits	~13,690 Years
14	80 bits	~109,500 Years
15	89 bits	~56,080,000 Years
20	119 bits	~Doesn't Matter

**Table only truly matters for randomly generated passwords*

Password Complexity versus Password Entropy

<https://blogs.technet.microsoft.com/msftcam/2015/05/19/password-complexity-versus-password-entropy/>

WHAT IS A CRYPTOGRAPHIC HASH?

A cryptographic hash function is a subclass of the general hash function which possesses properties lending its use in cryptography. Cryptographic hash functions are mathematical algorithms which map data of any size to a string containing a fixed length, and should make it infeasible to reverse. For instance, the string “password,” when mapped using the MD5 hash function, returns a fixed length 32 character string “5f4dcc3b5aa765d61d8327deb882cf99”. The 32 character string cannot theoretically be reversed with any other mapped input data except “password”. The current method of recreating this input data “password” is through a dictionary/mask/brute-force attack of all possible inputs matching the hashed value; also called a pre-image attack. Generally speaking, hash functions should possess the below characteristics:

- Be computationally infeasible to find two different sets of input data with the same hash value (also called a collision).
- The hash value should be “quick” to compute (i.e. > ~1 second).
- It should be difficult to generate the input data Just by looking at the hash value.
- One simple change to the input data should drastically change the resultant hash value.

How Hash Algorithms Work

<http://www.metamorphosite.com/one-way-hash-encryption-sha1-data-software>

MARKOV CHAINS

Markov Chains are created, for our password cracking purposes, by statistical analysis of a large list of passwords/words (i.e. the RockYou password dataset). The

resultant analysis of these words and their per-position character frequency/probability are stored in a table. This table is referenced when performing brute-force/mask attacks to prevent having to generate password candidates in a sequential order, which is very inefficient. Instead, the most common characters are attempted first in order of preceding character probability. So let's see sequential brute-force ?a?a?a?a with out Markov Chains applied:

aaaa	aaad	aaag
aaab	aaae	aaah
aaac	aaaf

Now the same brute-force attack with Markov Chains applied:

sari	aari	pari
mari	cari	2ari
1ari	bari

Markov Chains predict the probability of the next character in a password based on the previous characters, or context characters. It's that simple.

PROBABILISTIC CONTEXT-FREE GRAMMARS (PCFG)

A Probabilistic Context Free Grammar (PCFG) consists of terminal and nonterminal variables. Each feature to be modeled has a production rule that is assigned a probability, estimated from a training set of RNA structures. Production rules are recursively applied until only terminal residues are left. The notion supporting PCFGs is that passwords are constructed with template structures and terminals that fit into those structures. For example, the password candidate 'passwordl23!' is 8 letters, 3 digits, 1 special and would be noted as 'L₈D₃S₁'. A password's probability of occurring is the probability of its structure, multiplied by those of its underlying terminals.

NEURAL NETWORKS

Artificial Neural Networks or Neural Networks (NN) is a machine-learning technique composed of nodes called Artificial Neurons, just like the brain possesses. Such systems use Machine Learning to approximate highly dimensional functions and progressively learn through examples of training set data, or in our case a large password dump. They have shown initial promise to be effective at generating original yet representative password candidates. Advantages to NN's for password cracking are the low overhead for storing the final NN model, approximately 500kb, and the ability to continually learn over time through retraining or transfer learning.

APPENDIX

APPENDIX

TERMS

BRUTE-FORCE ATTACK - the act of trying every possible combination of a given keyspace or character set for a given length

DICTIONARY - a collection of commons words, phrases, keyboard patterns, generated passwords, or leaked passwords, also known as a wordlist

DICTIONARY ATTACK - using a file containing common or known password combinations or words in an attempt to match a given hashing function's output by running said words through the same target hashing function

HASH - the fixed bit result of a hash function

HASH FUNCTION - maps data of arbitrary size to a bit string of a fixed size (a hash function) which is designed to also be a one-way function, that is, a function which is infeasible to invert

ITERATIONS - the number of times an algorithm is run over a given hash

KEYSPACE - the number of possible combinations for a given character set to the power of it's length (i.e. charset^{length})

MASK ATTACK - using placeholder representations to try all combinations of a given keyspace, similar to brute-force but more targeted and efficient

PASSWORD ENTROPY - an estimation of how difficult a password will be to crack given its character set and length

PLAINTEXT - unaltered text that hasn't been obscured or algorithmically

altered through a hashing function

RAKING - generating random password rules/candidates in an attempt to discover a previously unknown matching password pattern

RAINBOW TABLE - a precomputed table of a targeted cryptographic hash function of a certain minimum and maximum character length

RULE ATTACK - similar to a programming language for generating candidate passwords based on some input such as a dictionary

SALT - random data that used as additional input to a one-way function

WORDLIST - a collection of commons words, phrases, keyboard patterns, generated passwords, or leaked passwords, also known as a dictionary

TIME TABLE

60 seconds	1 minute
3,600 seconds	1 hour
86,400 seconds	1 day
604,800 seconds	1 week
1,209,600 seconds	1 fortnight
2,419,200 seconds	1 month (30days)
31,536,000 seconds	1 year

e4821d16a298092638ddb7cadc26d32f = letmein123456Netmux

10 CRACK COMMANDMENTS

1. Thou shalt know hash types and their origin/function
2. Thou shalt know cracking software strengths & weaknesses
3. Thou shalt study & apply password analysis techniques
4. Thou shalt be proficient at hash extraction methods
5. Thou shalt create custom/targeted dictionaries
6. Thou shalt know thy cracking rigs capabilities
7. Thou shalt understand basic human psychology/behavior
8. Thou shalt create custom masks, rules, and Markov chains
9. Thou shalt continually experiment with new techniques
10. Thou shalt support thy fellow cracking community members

JOHN THE RIPPER HELP MENU

John the Ripper password cracker, version 1.8.0-jumbo-1 [darwin15.6.0 64-bit
AVX2-autoconf]

Copyright
Homepage:

(c) 1996-2014 by Solar Designer and others
<http://www.openwall.com/john/>

Usage: john [OPTIONS] [PASSWORD-FILES]

--single[=SECTION]	“single crack” mode
--wordlist[=FILE] --stdin	wordlist mode, read words from FILE or stdin
--pipe	like --stdin, but bulk reads, and allows rules
--loopback[=FILE]	like --wordlist, but fetch words from a .pot file
--dupe-suppression	suppress all dupes in wordlist (and force preload)
--encoding=NAME	input encoding (eg. UTF-8, ISO-8859-1). See also doc/ENCODING and --list=hidden-options.
--rules[=SECTION]	enable word mangling rules for wordlist modes
--incremental[=MODE]	“incremental” mode [using section MODE]
--mask=MASK	mask mode using MASK
--markov[=OPTIONS]	“Markov” mode (see doc/MARKOV)
--external=MODE	external mode or word filter
--stdout[=LENGTH]	just output candidate passwords [cut at LENGTH]
--restore[=NAME]	restore an interrupted session [called NAME]
--session=NAME	give a new session the NAME
--status[=NAME]	print status of a session [called NAME]
--make-charset=FILE	make a charset file. It will be overwritten
--show[=LEFT]	show cracked passwords [if =LEFT, then uncracked]
--test[=TIME]	run tests and benchmarks for TIME seconds each
--users=[-]LOGIN UID[...]	[do not] load this (these) user(s) only
--groups=[-]GID[...]	load users [not] of this (these) group(s) only
--shells=[-]SHELL[...]	load users with[out] this (these) shell(s)

--salt=[-]COUNT[:MAX] only
load salts with [out] COUNT [to MAX] hashes

--save-memory=LEVEL enable memory saving, at LEVEL 1..3
this node's number range out of TOTAL count

--fork=N fork N processes

--pot=NAME pot file to use

--list=WHAT list capabilities, see --list=help or doc/OPTIONS

--devices=N[...] devices) set OpenCL device(s) (list using --list=opencl-

--format=NAME force hash type NAME:

HASHCAT HELP MENU

hashcat 3.6 - advanced password recovery

Usage: hashcat [options]... hash[hash-file|hccapxfile] [dictionary|mask| directory]...

- [Options] -

Options Short / Long	Description
-m, --hash-type	Hash-type, see references below
-a, --attack-mode	Attack-mode, see references below
-V, --version	Print version
-h, --help	Print help
--quiet	Suppress output
--hex-charset	Assume charset is given in hex
--hex-salt	Assume salt is given in hex
--hex-wordlist	Assume words in wordlist are given in hex
--force	Ignore warnings
--status	Enable automatic update of the status screen
--status-timer	Sets seconds between status screen updates to X
--machine-readable	Display status view in machine-readable format
--keep-guessing	Keep guessing hash after it has been cracked
--loopback	Add new plains to induct directory
--weak	Threshold X to stop checking for weak hashes
--markov-hcstat	Specify hcstat file to use
--markov-disable	Disables markov-chains, classic brute-force
--markov-classic	Enables classic markov-chains, no per-position
-t, --markov-threshold	Threshold X to stop accepting new markov-chains
--runtime	Abort session after X seconds of runtime
--session	Define specific session name
--restore	Restore session from --session
--restore-disable	Do not write restore file
--restore-file-path	Specific path to restore file
-o, --outfile	Define outfile for recovered hash
--outfile-format	Define outfile-format X for recovered hash
--outfile-autohex-disable	Disable the use of \$HEX[] in output plains
--outfile-check-timer	Sets seconds between outfile checks to X
-p, --separator	Separator char for hashlists and outfile
--stdout	Do not crack a hash, print candidates only
--show	Compare hashlist with potfile; show cracked
--left	Compare hashlist with potfile; show uncracked
--username	Enable ignoring of usernames in hashfile
--remove	Enable removal of hashes once they are cracked
--remove-timer	Update input hash file each X seconds
--potfile-disable	Do not write potfile
--potfile-path	Specific path to potfile
--encoding-from	Force internal wordlist encoding from X
--encoding-to	Force internal wordlist encoding to X
--debug-mode	Defines the debug mode 1-4
--debug-file	Output file for debugging rules
--induction-dir	Specify induction directory to use for loopback
--outfile-check-dir	Specify outfile directory to monitor for plains
--logfile-disable	Disable the logfile
--hccapx-message-pair	Load only message pairs from hccapx matching X
--nonce-error-corrections	BF size range to replace AP's nonce last bytes
--truecrypt-keyfiles	Keyfiles to use, separated with commas
--veracrypt-keyfiles	Keyfiles to use, separated with commas
--veracrypt-pim	VeraCrypt personal iterations multiplier
-b, --benchmark	Run benchmark

--speed-only	Return expected speed of the attack, then quit
--progress-only	Return ideal step size and time to process
-c, --segment-size	Sets size in MB to cache from the wordfile to X
--bitmap-min	Sets minimum bits allowed for bitmaps to X
--bitmap-max	Sets maximum bits allowed for bitmaps to X
--cpu-affinity	Locks to CPU devices, separated with commas
-I, --opencl-info	Show info on detected OpenCL platforms/devices
--opencl-platforms	OpenCL platforms to use, separated with commas
-d, --opencl-devices	OpenCL devices to use, separated with commas
-D, --opencl-device-types	OpenCL device-types to use, separate with commas
--opencl-vector-width	Manually override OpenCL vector-width to X
-w, --workload-profile	Enable a specific workload profile, 1-4
-n, --kernel-accel	Workload tuning, set outerloop step size to X
-u, --kernel-loops	Workload tuning, set innerloop step size to X
--nvidia-spin-damp	Workaround NVIDIA's CPU burning loop bug
--gpu-temp-disable	Disable temperature, fanspeed reads, triggers
--gpu-temp-abort	Abort if GPU temperature reaches X degrees C
--gpu-temp-retain	Try to retain GPU temperature at X degrees C
--powertune-enable	Enable power tuning. Restores settings
--scrypt-tmto	Manually override TMTO value for scrypt to X
-s, --skip	Skip X words from the start
-l, --limit	Limit X words from the start + skipped words
--keyspace	Show keyspace base:mod values and quit
-j, --rule-left	Single rule applied to word from left wordlist
-k, --rule-right	Single rule applied to word from right wordlist
-r, --rules-file	Multiple rules applied to word from wordlists
-g, --generate-rules	Generate X random rules
--generate-rules-func-min	Force min X functions per rule
--generate-rules-func-max	Force max X functions per rule
--generate-rules-seed	Force RNG seed set to X
-1, --custom-charset1	User-defined charset ?1
-2, --custom-charset2	User-defined charset ?2
-3, --custom-charset3	User-defined charset ?3
-4, --custom-charset4	User-defined charset ?4
-i, --increment	Enable mask increment mode
--increment-min	Start mask incrementing at X
--increment-max	Stop mask incrementing at X

- [Hash modes] -

#	Name	Category
900	MD4	Raw Hash
0	MD5	Raw Hash
5100	Half MD5	Raw Hash

HASH CRACKING BENCHMARKS

****HASH CRACKING BENCHMARK tables are meant to be a reference to enable users to gauge how SLOW or FAST a hashing algorithm is before formulating an attack plan. Nvidia GTX2080 was chosen as the default due to its prevalence among the cracking community and it's position as a top performing GPU card.*
